Introduction

The existing weir in the Yahara River in Stoughton was originally built to divert water for the generation of hydroelectric power. There is no longer power generated at the site, and the City of Stoughton is interested in replacing the dam with a river park and creating a public amenity. Recreation Engineering and Planning Inc. (REP) was contracted to develop a design that would eliminate the current public safety hazard at the dam, improve river access, improve fish passage and habitat, and create a recreational amenity close to downtown Stoughton.

The weir and the proposed project are located within the delineated FEMA floodway of the Yahara River, requiring a floodplain analysis to demonstrate no adverse impact to the floodplain as a result of the project. The purpose of this report is to describe the analysis of the regional flood that would result upon completion of the project. This report summarizes the procedure and results of the hydraulic analysis performed. The proposed conditions modeled are consistent with the most recent design plans.

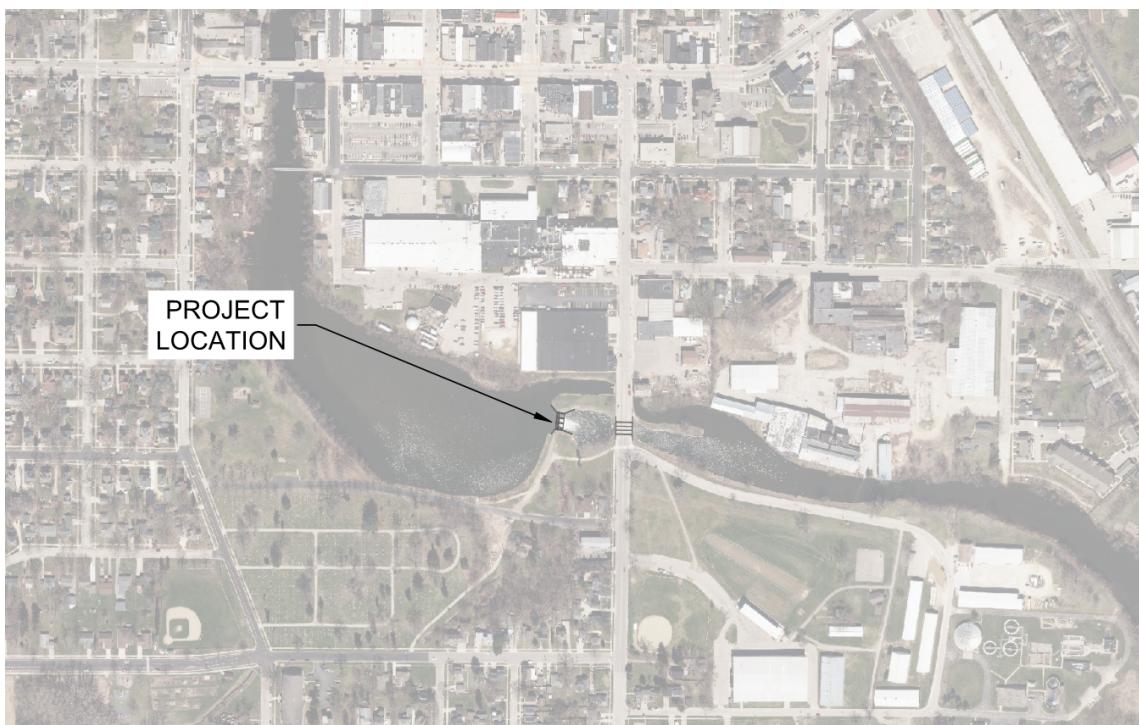

Figure 1. Project vicinity map.

Figure 2. Existing Stoughton Dam (Image date: Oct 22, 2019, flow ~930cfs)

Figure 3. Existing box culverts under 4th St (Image date: Oct 22, 2019, flow ~930cfs)

Hydrology

USGS gage 05429700 is located just upstream of the project site at the Forton Street bridge. The period of record for this gage is November 2003 to present.

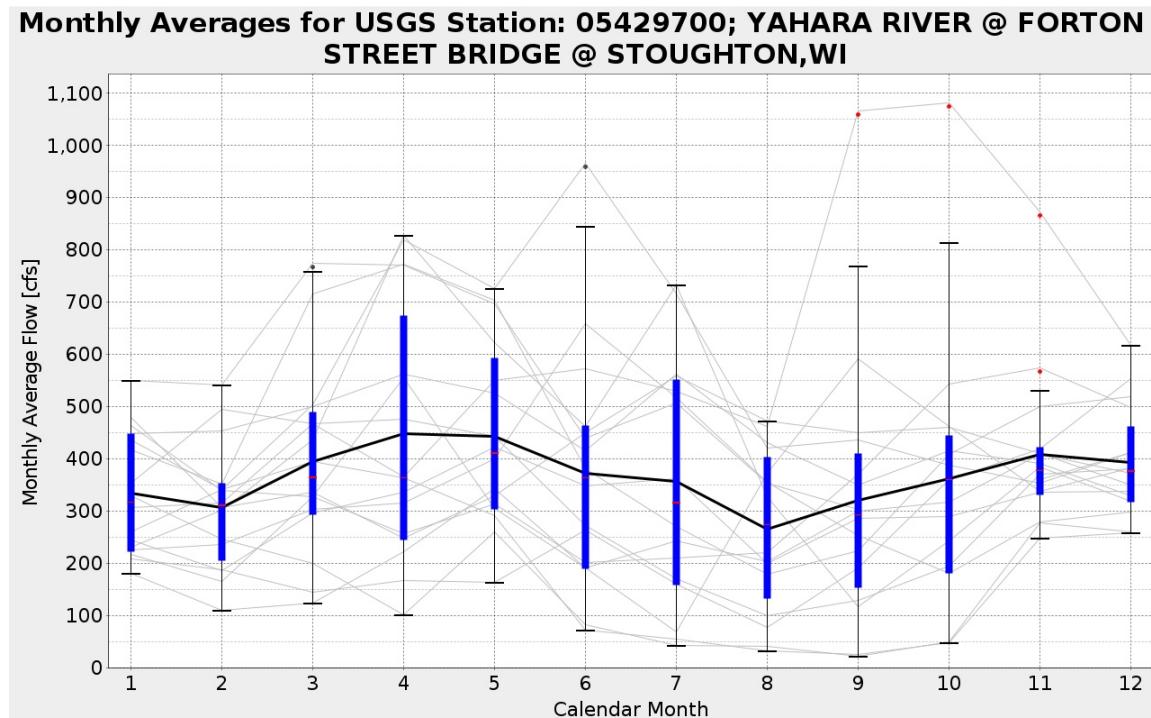

Figure 4. Monthly average flows connected by the bold black line. A box plot is shown for each month, with the blue bar representing the interquartile range. The monthly averages for each individual month of record are shown in light grey.

The mean annual flow is 380cfs, with relatively little fluctuation throughout the year. Spring has the highest average flows (almost 450cfs for April and May), while September has the lowest average flow at under 300cfs.

The project area is located within a floodplain study area mapped by the Federal Emergency Management Agency (FEMA). The current Flood Insurance Study (FIS) for Dane County, WI has an effective date of June 16, 2016. The 1% annual-chance discharge (base flood) according to the current FIS for this reach of the Yahara River is 1,232 cubic feet per second (cfs) upstream of 4th street, and 1,304cfs downstream of 4th Street. The base flood is referred to as the regional flood by the Wisconsin Department of Natural Resources (DNR).

Current and Duplicate Effective Model

The current effective models for the Yahara River through the project area were downloaded from the Wisconsin DNR Surface Water Data Viewer. Both the Yahara – Lake Waubesa to Stoughton and the Yahara – Stoughton to Rock River models were downloaded, since the division of the two models is located immediately adjacent to the downstream project boundary. The hydraulic models are one-dimensional HEC-RAS models. Based on correspondence with City of Stoughton, REP understands these are the most current hydraulic models of the reach. According to the DNR model descriptions, the final runs were performed in HEC-RAS v3.1.1. The modeling described in this report utilized HEC-RAS v5.0.7.

HEC-RAS geometry data from the Yahara – Stoughton to Rock River model was imported into the Yahara – Lake Waubesa to Stoughton model to create an extended Yahara River floodplain model. Geometry from the upstream end of the model to cross-section 58928 H were imported, including the Dunkirk Dam which influences water levels near Stoughton. The steady flow data was updated to match the flows in both models, and the downstream boundary condition known water surface elevations were updated to match the water levels at cross-section 58928 H. Wisconsin DNR HEC-HMS discharges (10-yr, 25-yr, 50-yr, 100-yr, and 500-yr) were run through the model, and water surface elevations in the combined effective model were reproduced at all cross-sections. Base flood (regional flood) elevations from the effective FIS were reproduced at all published FEMA cross sections. This model is referred to as the Duplicate Effective Model.

Existing Conditions Model

Bathymetric Survey

On June 24, 2019 a team with Great Lakes Ecological Monitoring LLC collected bathymetric data from the Yahara River in the vicinity of the 4th St culverts. In the mill pond upstream of the weir, bathymetry data was collected by Interfluve during their sediment sampling work in 2019. Strand Associates, Inc (Strand) performed topographic surveys, including bathymetric data, in 2020 and 2021. All survey data collected at the site was merged into a single base file by Strand surveyors, which was used by REP to update existing conditions cross-section geometry with the more accurate topographic information.

Model Update

REP modified the Duplicate Effective Model to create the Existing Conditions Model by incorporating the more detailed topographic information obtained from the surveys. Cross-sections were added and existing cross-sections were updated from RS 89196 to RS 86607. Cross-sections were added to provide sufficient detail to compare existing to proposed geometry and resulting water surface elevations. 28 cross-sections were added in the area upstream of the Stoughton Dam between RS 89196 and RS 87727, two cross-

sections were added between the Stoughton Dam and the 4th St culverts, and 33 cross-sections were added below 4th St between RS 87420 and RS 86607.

All roughness values from the effective model were maintained. For new cross-sections, Manning's n values were selected consistent with the values in the cross-sections in the effective model. The inline structure representing the Stoughton Dam remained unchanged from the effective model, as well as the bridge culvert data representing 4th St. The inline structure representing the concrete wall weir immediately upstream of the 4th St culverts was removed from the model. The weir was removed during the 2010 embankment and spillway reconstruction. Ineffective flow areas in the existing headrace, tailrace, surrounding the dam embankment, and downstream of 4th St embankment were left consistent with the effective model.

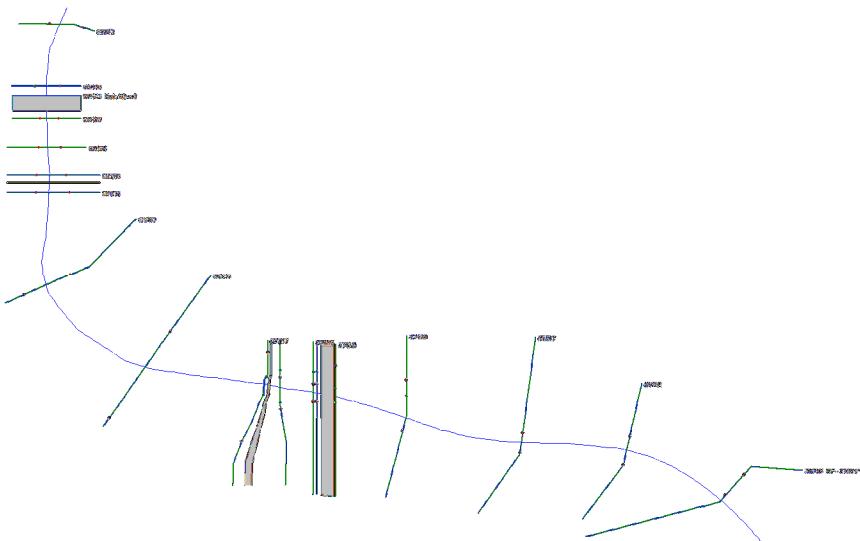

Figure 5. Model geometry from the Duplicate Effective Model in the project area

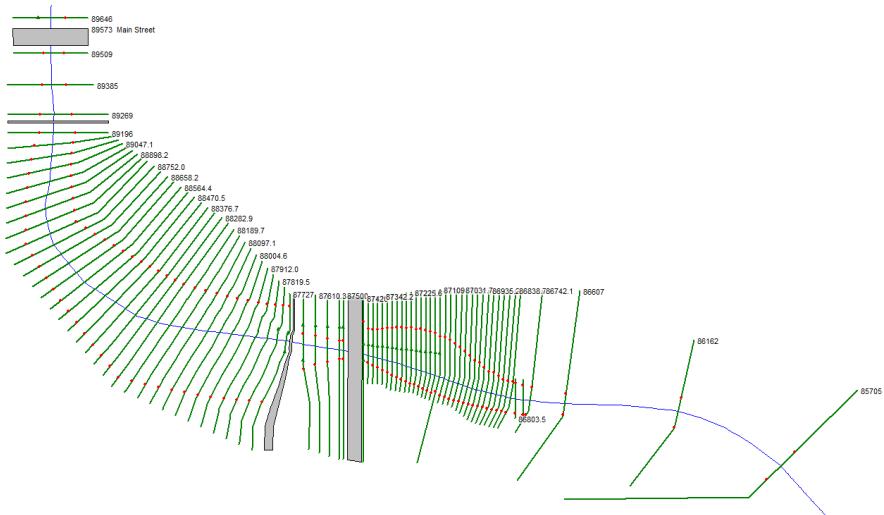

Figure 6. Model geometry from the Existing Conditions Model in the project area

Proposed Conditions Model

The Existing Conditions Model was then modified to represent proposed conditions. Proposed dam removal, grading, boulder structures, and trail underpass were inserted to represent the proposed design. This model is referred to as the Proposed Conditions Model. The proposed geometry is consistent with the most recent design plans.

No change was made to the cross-sections in the mill pond above RS 87727 where no grading is proposed. The inline structure representing the Stoughton Dam was removed to represent the removal of the dam gates and superstructure. The proposed dam embankment crest geometry is represented in the cross-section at RS 87727. A new cross-section was added at RS 87692.5 in place of the old inline structure. Upstream and downstream of 4th St, cross-section geometry was updated to reflect the proposed project, including filling of the headrace and tailrace, novice channel grading, boulder structures, and other proposed improvements. All roughness values remained unchanged, and the ineffective flow areas from the existing conditions model were left unchanged.

A bridge was added at RS 86785 to represent the proposed pedestrian bridge at that location. The proposed project includes a trail underpass under 4th St. The trail will run through the north culvert under 4th St. A wall is proposed along the trail immediately upstream and downstream of the underpass, separating the trail from the Yahara River during normal flows. At periods of high flow, the wall will be overtopped and the culvert can be used to convey flood flows. To represent the proposed underpass in the model, the proposed wall and trail geometry was inserted, and a levee and permanent ineffective flow area was added to all cross-sections with the proposed separator wall. The “levee” in the model is the top of the separator wall, not allowing flow over the trail until the wall is overtopped. The area below the top of the wall is modeled as a permanent ineffective flow area to account for the hydraulic effects of the separator wall when it is overtopped and the culvert is conveying flow.

Results

The resulting water surface elevations from the current effective base flood discharge (1,232cfs upstream of 4th St, and 1,304cfs downstream of 4th St) were evaluated for all model runs, and pre- and post- project conditions were compared to the published current effective FIS flood elevations. This is referred to as the regional flood by DNR. The project meets the requirements for no-rise conditions within the regulatory floodplains of the Yahara River.

The table on the following page contains the modeled water surface elevations (WSE) for the regional flood for the Duplicate Effective model, Existing Conditions model, and Proposed Conditions model. Based on the hydraulic analysis described and the modeled results, the proposed conditions modeled meet no-rise requirements.

Yahara River Regional Flood WSE Comparison Table

Data from effective FEMA FIS (2016)			Data from DNR model		Data from existing model		Data from proposed model		Calculated Difference
1	2	3	4	5	6	7	7 - 6	Proposed - Existing

SPECIAL ECON HAZARD AREAS (SEHAS) SUBJECT TO

HUNDRED BY THE 1% ANNUAL CHANCE FLOOD
A hundred is one chance flood (1% per year), also known as the base flood. The term "base flood" means the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area (SFHA) is the area of Special Flood Hazard. Areas of Special Flood Hazard are delineated by the Federal Emergency Management Agency (FEMA). The Base Flood Elevation is the water level of the 1% annual chance flood.

It is the desire of a stream owner adjacent floodplain areas that much
soil loss be prevented. The author therefore has one for owners of floodplain
areas.

OTHER FLOOD AREAS

A rate of 0.2% annual chance of flood; areas C^* , 1% and 2% chance flood, a weight of capital loss of less than 1 foot or with debris areas less than mile, and areas protected by a breach from 1% annual chance flood.

OTHER AREAS
Areas determined to be outside the 0.2% annual chance floodplain.
Areas in which flood waters are unlikely to reach, but possible.

OTHERWISE PROTECTED AREAS (OPAs)
OPAs are normally outside National or Adjacent to Special Food Hazard Areas

The figure shows a map of the Kurnool District area. A thick blue line outlines the 'Flooding Boundary'. A thin red line outlines the 'Zone D boundary'. The map also features several rivers and lakes, including the Krishna River, Tadikona Lake, and various tanks like Ponnampet, Chintalapudi, and Kothapet tanks. A scale bar indicates distances up to 10 km, and a north arrow is present.

SPECIAL FLOOD HAZARD AREAS (SFHA)
INUNDATION BY THE 1% ANNUAL
CHANCE FLOOD (100-year flood), also known as the
base level of flooding associated with a given year's chance
flood. The 1% annual chance of flooding by the 100-year chance flood. Areas
 subject to flooding by the 1% annual chance flood. Are
 zones A, AE, AH, AO, AF, AFH, XE, VE.
 of the 1% annual chance flood.

An aerial photograph showing a residential neighborhood. A specific area is outlined in blue and filled with a dotted pattern, labeled 'ZONE 1'. The surrounding area includes several houses, roads, and green spaces.

An aerial photograph of a agricultural field. A small, roughly rectangular area in the center-right is outlined in blue and contains a fine blue grid, possibly representing a survey plot or a specific area of interest. The surrounding land appears to be a mix of crops and fallow fields.

An aerial photograph of the Dane County Unincorporated Area, centered around the intersection of University Avenue and State Street. The area features a mix of residential neighborhoods with single-family homes, larger apartment complexes, and various commercial buildings. A prominent industrial or institutional facility with multiple large buildings and parking lots is visible on the right side. The terrain is mostly flat, with some green spaces and trees scattered throughout the developments.

Individuals description, and/or location information for benchmark stations. The survey was open to the public from April 1, 2019 through June 30, 2019. Survey results were used to develop a map of the locations of the most frequently observed species. The survey was conducted by the Florida Fish and Wildlife Conservation Commission (FWC). This annual phenology survey has been conducted since 2000 to detect changes in the timing of seasonal events such as breeding, migration, and molting. The survey is conducted in the same manner each year to facilitate comparison between years. The survey is conducted in the same manner each year to facilitate comparison between years.
